# 1 STAIRMAND Cyclone

**Author:** Alexandre Douce (2001), RENUA

**Last update:** 8/10/2020

**Key-words:** Incompressible, Lagrangian Two-Phase, Turbulent ( $R_{ij} - \varepsilon$  *SSG*), one-way and two-way coupling.

## 1.1 Test Case Description

### 1.1.1 Purpose

In general, the cyclones are an example of a two-phase separator which are used to separate solid particles contained in a gas flow into two flows: the gas which leaves the cyclone through the upper exit and the particles which are collected at the bottom of the cyclone.

Within this validation test case, the air turbulent flow in the cyclone is simulated without and with an injection of particles. The correct prediction of the monophasic simulation is essential for the evaluation of the separating power of the device (aspect which generally constitutes the ultimate goal of studies).

The goal of this study is to check if the turbulence model  $R_{ij} - \varepsilon$  *SSG* established in *Code\_Saturne* predicts the "double spin" structure of the flow.

### 1.1.2 Setup Description

The geometry is presented in figure 1.1.

Figure 1.1: Test case geometry.

The fluid inlet is tangential to the axis of the cylinder. The flow then goes down along the spiral wall to the bottom of the cyclone, then the fluid goes up through the central part of the cyclone in order to exit through the upper outlet. The geometrical characteristics of the Stairmand cyclone are summarized in table 1.1:

D (mm)	De (mm)	H (mm)	h (mm)	a (mm)	b (mm)	S (mm)	B (mm)
200	100	800	300	100	40	100	72

Table 1.1: Dimensions of the Stairmand cyclone.

The particles are injected all at the same time [4].

### 1.1.3 Fluid characteristics

- Cinematic viscosity :  $\nu = 10^{-5} \text{ m}^2 \cdot \text{s}^{-1}$
- Density :  $\rho = 1 \text{ kg/m}^3$
- Volumic flow rate of  $0.12 \text{ m}^3/\text{s}$  is imposed at the inlet corresponding to a reference velocity of  $U_0 = 30 \text{ m} \cdot \text{s}^{-1}$  (inlet velocity).
- Reynolds number :  $Re = U_0 \cdot De / \nu = 3 \cdot 10^5$

Remarks : A volumic flow rate imposed at the inlet gives better results than a uniform velocity.

EDF R&D	Validation of <i>Code_Saturne</i> 6.2-alpha (Appendix 1)	????-????-2020-????-EN  Version 1.0
---------	---	---

### 1.1.4 Particles characteristics

The particles have a density of  $2500 \text{ kg/m}^3$  and their diameters are ranging between 0.5 and 5 *mm*.

## 1.2 Numerical setup

### 1.2.1 Numerical modelling

- **Type of calculation :**
  - Continuous phase: incompressible, turbulent, 3D, High Reynolds.
  - Dispersed phase: solid particles, one-way coupling.
  - Dispersed phase: solid particles, two-way coupling.
- **Gravity:** No
- **Turbulence model:**  $R_{ij} - \varepsilon$  *SSG*
- **Passive scalar:** a passive scalar is introduced at the inlet to follow the "convergence" of the calculation; as it does not represent any physical quantity, it is not referred to in the rest of the study.

EDF R&D	Validation of <i>Code_Saturne</i> 6.2-alpha (Appendix 1)	???-???-2020-?-EN  Version 1.0
---------	---	--------------------------------------

### 1.2.2 Mesh

Figure 1.2: Clips of the mesh.

Figure 1.3: Mesh.

**Coordinate system:** Cartesian, origin at the bottom of the output skirt, and in the center of the cylinder (see fig 1.2)

**Process used to build the mesh :** it is a mesh generated with ESTET, which has been transformed via the ESTET2SOLCOM tool into a geometric data file directly usable by *Code\_Saturne*.

**Number of cells :** 128,070

**Number of internal faces :** 376,936

**Number of boundary faces :** 18,550

The beginning of the listing of *Code\_Saturne* gives the angles of non-orthogonality of the mesh:

#### HISTOGRAMMES DES ANGLES DE NON ORTHOGONALITE

Faces internes					
00-15	15-30	30-45	45-60	60-75	75-90
232013	112316	23006	7021	2580	0
Faces de bord					
00-15	15-30	30-45	45-60	60-75	75-90
9688	3251	2061	1398	1408	744

We note that a certain number of elements have high non-orthogonality angles, which means that it is a medium quality mesh. This is due to the presence of strongly "flattened" cells on the wall (figure 1.3).

### 1.2.3 Boundary and Initial Conditions

- **Fluid boundary conditions :**

BC	Name	Fluid boundary conditions
BC_1	Inlet	inlet
BC_2	Outlet_up	outlet
BC_3	Walls	wall
BC_4	Outlet_bot	outlet

- **Conditions for the velocity  $\mathbf{u} = (u, v, w)$**

**Inlet :** Dirichlet condition :

- volumic flow rate of  $0.12 \text{ m}^3/\text{s}$  is imposed at the inlet corresponding to a reference velocity of  $U_0 = 30 \text{ m} \cdot \text{s}^{-1}$

**Outlets :** standard free outlet type 9.

**Walls :** friction condition (wall model with two 2 scale model).

**Initial Conditions :**  $u = 0$  ;  $v = 0$  ;  $w = 0$ .

- **Boundary conditions for the pressure**

**Free Outlets :** Dirichlet (standard, *i.e.* as  $\frac{\partial}{\partial n} \frac{\partial P}{\partial \tau} = 0$ ).

**Elsewhere :** homogeneous Neumann.

- **Conditions for the scalars**

- *Variables for the turbulence*

The values for the turbulence are calculated from the hydraulic diameter for the inlet and all the other default parameters are calculated by *Code\_Saturne*.

$S$ , Inlet section, is  $4 \cdot 10^{-3} \text{ m}^2$ ,

$P$ , Wet perimeter, is  $0.28 \text{ m}$ ,

$D_h$ , Hydraulic diameter, is :  $\frac{4 \cdot S}{P} = 0.057 \text{ m}$ ,

$Re_H$ , Reynolds number based on the hydraulic diameter, is :  $Re_H = \frac{U \cdot D_H}{\nu}$ , so  $Re_H = 1.7 \cdot 10^5$

$\lambda$  is so  $0.184 Re_H^{-0.2}$ , so  $\lambda = 0.016$

and we obtain  $u^* = \sqrt{\frac{\lambda}{8}} U$  with  $U = 30 \text{ m} \cdot \text{s}^{-1}$ , so  $u^* = 1.36 \text{ m} \cdot \text{s}^{-1}$ .

**Inlet :** Dirichlet condition

**Outlets :** Standard free outlet

**Walls :** Condition for a turbulent wall.

**Initial conditions :** calculated from  $U_{ref} = U_0$ .

- *Passive scalar*

**Inlet :** Dirichlet condition (value = 1)

**Elsewhere :** homogeneous Neumann.

**Initial conditions :** null value.

- **Particle boundary conditions :**

BC	Name	Particle boundary conditions
BC_1	Inlet	inlet
BC_2	Outlet_up	outlet
BC_3	Walls	perfect rebound
BC_4	Outlet_bot	outlet

EDF R&D	Validation of <i>Code_Saturne</i> 6.2-alpha (Appendix 1)	????-????-2020-????-EN  Version 1.0
---------	---	---

The diameter range of the particles has been discretised as follows, [0.5; 1; 1.5; 2; 3; 4; 5] *mm*. For each class (diameter of particles), a number of 100 particles is released (this number is identical for each class).

### 1.2.4 Numerical schemes

For the two turbulence models, all the numerical parameters are those defined by default in *Code\_Saturne*. We use a centered-upwind scheme, configured to be 100% centered (BLENCV=1), as the convection scheme.

### 1.2.5 User coding

- **cs\_user\_extra\_operations.f90** : in order to change the time step for a one-phase calculation (from  $10^{-4}$  to  $10^{-5}$  s) in order to avoid a jump during the restart for the two-phase calculation.

### 1.2.6 Calculation strategy

The runs are carried out in two steps. The first step is a one-phase calculation, without particles. This makes it possible to initialise the two-phase calculations. During the one-phase calculation, the time step is reduced in order to avoid a jump at the restart for the two-phase calculations. Because the particles are injected at the beginning of the two-phase calculations, it was important to avoid the jump at the restart.

#### • One-phase calculation

- **Restart:** NO
- **Maximum time :** 0.8 s
- **Time step:** constant (IDTVAR=0),  $10^{-4}$  s. then  $10^{-5}$  s. after  $t = 0.5$  s

#### • Two-phase calculation - One Way

- **Restart:** YES
- **Restart of the Lagrangian calculation:** NO
- **Total number of time steps (including one-phase calculation):** 100,000
- **Time step:** (IDTVAR=0),  $10^{-5}$  s
- **Stationary continuous phase:** NO (ISTTI0=0)
- **Turbulent dispersion model:**
  - \* For the two-phase calculation, the default complete model with the local rotation option is utilised.
- **Dynamic one-way coupling:** YES (IILAGR=1 and LTSDYN=1)
- **Total number of class for particles:** 7
- **Total number of particles injected for each class and at the first lagrangian iteration:** 100

#### • Two-phase calculation - Two Way

- **Restart:** YES
- **Restart of the Lagrangian calculation:** NO
- **Total number of time steps (including one-phase calculation):** 100,000
- **Time step:** (IDTVAR=0),  $10^{-5}$  s
- **Stationary continuous phase:** YES (ISTTI0=1)

EDF R&D	Validation of <i>Code_Saturne</i> 6.2-alpha (Appendix 1)	????-????-2020-????-EN  Version 1.0
---------	---	---

- **Turbulent dispersion model:**

\* For the two-phase calculation, the default complete model with the local rotation option is utilised.

- **Dynamic two-way coupling:** YES (IILAGR=2 and LTSDYN=1)

- **Total number of class for particles:** 7

- **Total number of particles injected for each class and at the first lagrangian iteration:** 100

## 1.3 Results

### 1.3.1 Run data

- **One-phase run**

- Inlet flow at the outlets: NO
- Number of clips on  $R_{ij} - \varepsilon$  in the listing: none
- Maximum CFL number of the order of 0.4 (very stable)

- **Two-phase run - One way coupling**

- Inlet flow at the outlets: NO
- Number of clips on  $R_{ij} - \varepsilon$  in the listing: none
- Maximum CFL number of the order of 0.4 (very stable)
- Percentage of lost particles: 0.0%

- **Two-phase run - Two way coupling**

- Inlet flow at the outlets: NO
- Number of clips on  $R_{ij} - \varepsilon$  in the listing: none
- Maximum CFL number of the order of 0.4 (very stable)
- Percentage of lost particles: 0.0%

### Convergence

- **One-phase run convergence**

Figure 1.5 gives the evolution of the axial component of velocity at five points,  $C_i$  (see the probe locations in the figure 1.4 and the table 1.2 to see the corresponding probe numbers).

Figure 1.4: *Probe locations.*

<i>Probe</i>	<i>Probe number</i>	<i>X</i>	<i>Y</i>	<i>Z</i>
$C_1$	1	0	0	-0.20
$C_2$	2	0	0	0
$C_3$	3	0	0.05	-0.1
$C_4$	4	0.05	0	-0.1
$C_5$	5	0.07	-0.07	0.05

Table 1.2: Coordinates of the probes (in  $m$ )

The figures below show the evolution of the convergence rate for  $0.8\text{ s}$ . We note the jump at  $t = 0.5\text{ s}$  when the time step is reduced from  $10^{-4}\text{ s}$  to  $10^{-5}\text{ s}$ . The simulation exhibits oscillations around the mean values.

EDF R&D	Validation of Code_Saturne 6.2-alpha (Appendix 1)	<p>????-????-2020-????-EN</p> <p>Version 1.0</p>
---------	--	--

Figure 1.5: One-phase calculation - Evolution of the axial velocity

- **Two-phase run convergence - One way coupling**

The figures below shows the evolution of the convergence rate for the one way coupling calculation. The simulation exhibits oscillations around the mean values.

Figure 1.6: Two-phase calculation - One way coupling - Evolution of the axial velocity

- **Two-phase run convergence - Two way coupling**

The figures below show the evolution of the convergence rate for the two way coupling calculation. The simulation exhibits oscillations around the mean values.

Figure 1.7: Two-phase calculation - Two way coupling - Evolution of the axial velocity

### 1.3.2 Results

Due to the fluctuations in the flowfield (seen in 1.5, 1.6, and 1.7), the velocity fields are time averaged from  $t = 0.6 \text{ s}$  to  $0.8 \text{ s}$  for the one-phase calculation and from  $t = 0.9 \text{ s}$  to  $1.45 \text{ s}$  for the two-phase calculations. Figures 1.8 and 1.9 present the profiles of the axial and tangential components of the instantaneous velocity in the cyclone according to horizontal sections for which experimental measurements are available in [2] at the last time step of the calculations, and the figures 1.10 and 1.11 present the same profiles with a time average.

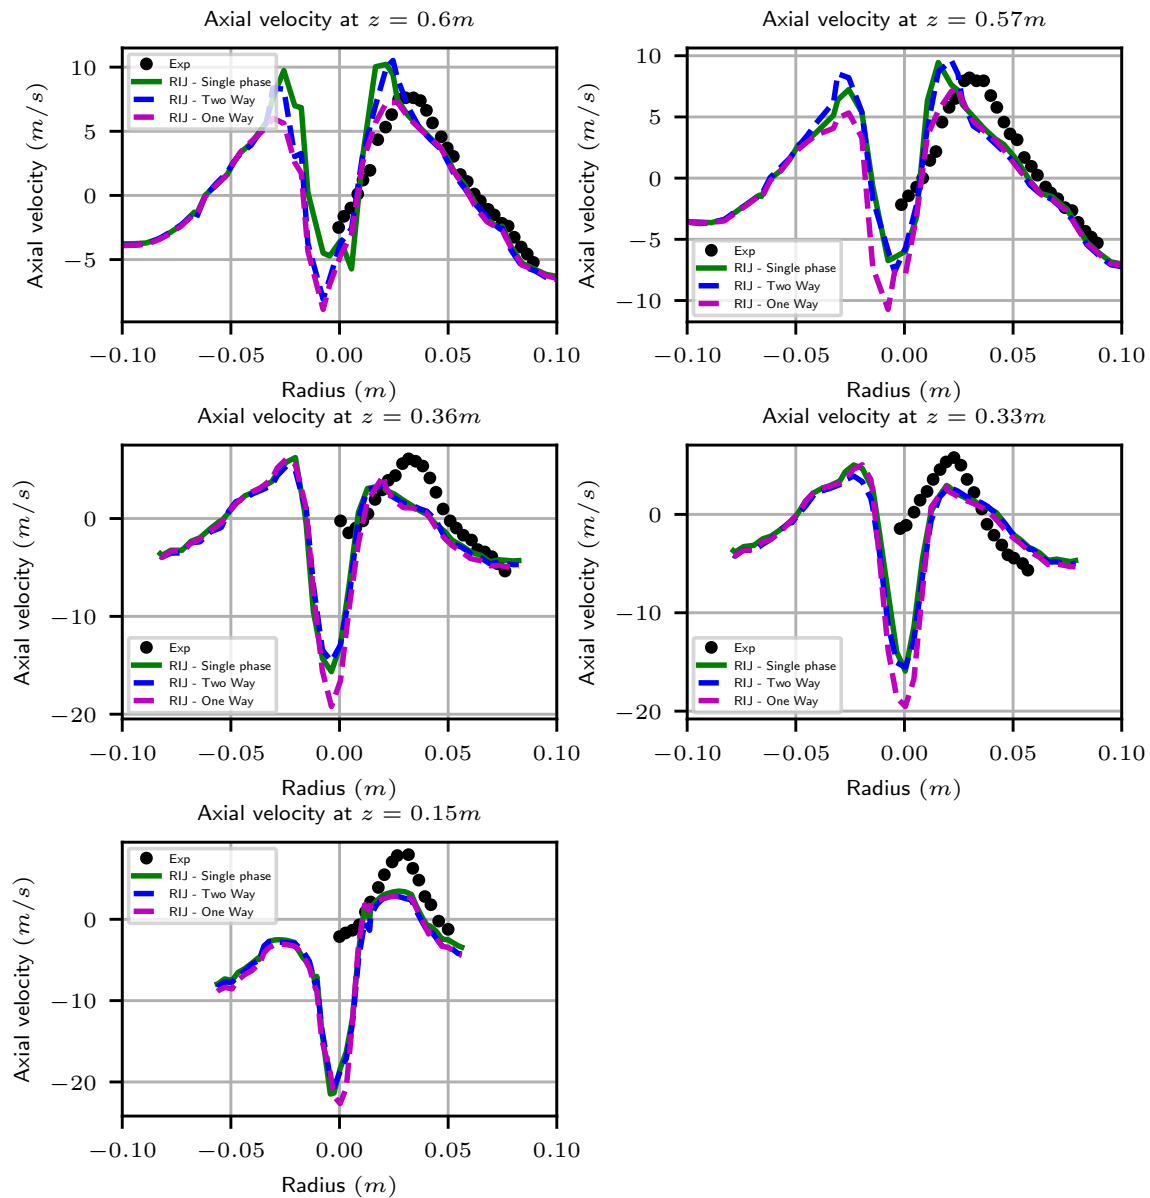

Figure 1.8: Axial velocity of the single and two-phase calculations compared to the experiment

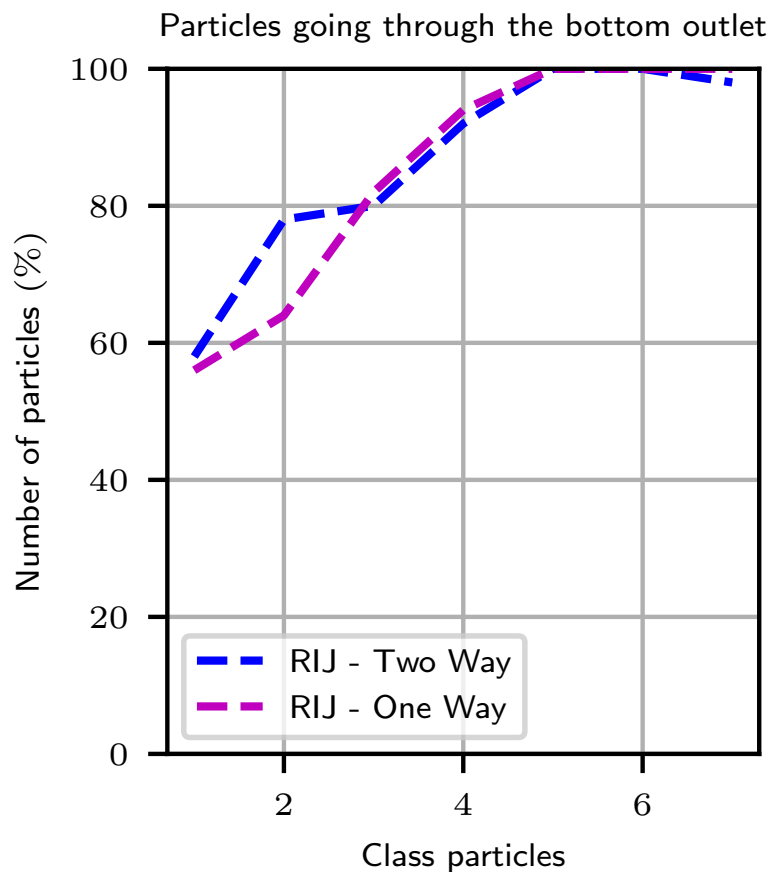

Figure 1.13: Particles going through the bottom outlet

### 1.3.3 Analysis and discussion

The flow field has an unsteady character in the simulations as seen experimentally in [2]. This is the reason why the computed flow fields were time averaged in order to plot the axial and tangential velocity components. The one-phase and the two-phase calculations produce, as expected, similar profiles for the axial and tangential velocity at different horizontal sections. The axial velocity component has a negative value at the center of the cyclone which is higher than the experimental one. For the two-way coupling calculation, the particles do not have a visible impact on the flow field. The axial velocities are accurately

EDF R&D	Validation of <i>Code_Saturne</i> 6.2-alpha (Appendix 1)	????-????-2020-????-EN  Version 1.0
---------	---	---

predicted at  $z = 0.6$  and  $0.57\text{ m}$  whereas the tangential velocities show a shift of the radius where there is the maximum tangential velocity between the experiment and the simulations. Based on the experimental data, the maximum tangential velocities are located at around  $r = 0.02$  and  $r = 0.05\text{ m}$ , depending on the  $z$  coordinate, while the simulations predict the locations of the maximum tangential velocities at around  $r = 0.01$  and  $r = 0.02\text{ m}$ . Between the maximum tangential velocities and the walls, the slopes of the velocity profiles are similar to those of the experiment.

For the two-phase calculations, the evolution of the number of particles is similar between the one-way and the two-way coupling solutions. The proportion of the total particles injected in the domain going through the bottom outlet, depending on the class of particles, has a similar selectivity curve in the one-way and the two-way coupling (i.e. around class 5 corresponding to a diameter of particles of  $3\text{ mm}$ ). Only for the second class ( $1\text{ mm}$ ) the two-way coupling has more particles going through the bottom outlet than the one-way calculation, but it is important to note that this difference of the selective curve around the second or the third class changes from one run to another.

In order to better understand the structure of the flow, a visual examination of several physical moments was done in a vertical section plane. We have thus been able to observe that model  $R_{ij}-\varepsilon$  SSG manages to reproduce the characteristic vertical velocity reversal at the bottom of the cyclone (unsteady). In addition, it can be seen that the double spin is not stabilized on the axis of the cyclone, but on the contrary moves in the vicinity of this axis.

In conclusion, the results obtained for this industrial case have the expected characteristics. In addition, it would be interesting to do a mesh dependency and time step analysis computations to see the impact on the selectivity curve.

---------	---	---

## 1.4 Archiving

The directory for the case is named: **CYCLONE**

The sub-directories are organised as follows:

**RIJ:** everything having to do with the single-phase calculation.

**DIPH\_OneWay**: everything having to do with the two-phase calculation in one way coupling.

**DIPH\_TwoWay**: everything having to do with the two-phase calculation in two way coupling.
